

# Critical Operating Constraints & Probabilistic Congestion Forecasting

## How to Prevent Short-Term and Long-Term Blackouts in California while Meeting Renewable Portfolio Standards?

California Energy Commission  
Transmission Research Program Colloquium  
Sacramento, California

September 11, 2008

Stephen Lee & Liang Min  
EPRI

# Outline

- Acknowledgement
- Why these two research topics?
- What were achieved?
- What this means for the future of California?

# Acknowledgement for Two Projects

- Sponsored by  
PIER Transmission Research Program 2006-2007
- TRP Project Managers: Jim Cole, Larry Miller,  
Virgil Rose
- Research Organization: EPRI
  - ◆ Steve Lee, Principal Investigator
  - ◆ Liang Min
  - ◆ Guorui Zhang
  - ◆ Peter Hirsch
- **CAISO Champions:**
  - ◆ Jim Detmers, VP of Operations
  - ◆ Armando Perez, retired VP of Planning
- EPRI Cost Sharing – prior research and workshop

Jim Detmers foresaw the need of this tool in 2005 and EPRI had done prior research that would enable this method to be tested.

# Why Critical Operating Constraints Forecasting (COCF)?

- Technology Challenge

- ◆ Not enough power plants in Southern California and not enough transmission capacities to bring power in
- ◆ Existing control center tools do not predict critical operating constraints
- ◆ Jim Detmers:

“Grid operators need a tool to predict when and where they will need to take emergency actions to overcome a transmission bottleneck. A 2-hour warning means preventing a blackout. We need this capability to prevent and solve power crisis during summer months”

Disclaimer: The photo and the quotation are unrelated.

- Solution

- ◆ Develop forecasts of critical operating constraints for the next 24 hours
- ◆ Simulate different power purchase scenarios
- ◆ If unavoidable, plan for load reduction in advance

# Why Probabilistic Congestion Forecasting (PCF)?

- Research Challenge
  - ◆ Uncertainties of short term and long term transmission congestion
  - ◆ Difficulties in siting and building more transmission lines
  - ◆ Effects of renewable generation and demand options on transmission congestion
- Solution
  - ◆ Develop short term and long term probabilistic forecasts of transmission congestion
  - ◆ Use the tools to evaluate different scenarios
- Future Work
  - ◆ **Studies to assess policy implications to manage transmission congestion**
  - ◆ **Wind Integration and Holistic Planning**

# What Uncertainties?

- Hydro power (drought, normal or wet)
- Weather effect on customer demand
- Equipment failures - generators or transmission on outage
- Power market and fuel price fluctuations
- Location and type of future power plants
- Increasing amounts of **Wind** and solar power present additional HUGE uncertainties for grid integration
- Future **Electric Vehicles** – charging load and emergency generation present both risk and opportunities for grid operation

# Tehachapi Wind Generation in April – 2005

# Questions for Audience

- After seeing this graph, would you say
- It is harder to forecast wind output in the short term?
- Or it is harder to forecast wind output in the long term?

## Answers:

Short-term wind forecast can be more accurate if more real-time weather data is available.

Long-term wind forecast accuracy is much harder to improve.

# Short-Term Wind Uncertainty

- Confidence about wind forecast gets better when the forecast window is shorter
- Assuming “Persistence” of current wind output is more accurate than using climatology for up to about 5 hrs
- Physics-based Event Forecast of **up or down ramps** of wind output is critical for grid operation

# Long-Term Wind Uncertainty

Customer Demand

Average Wind Output

- Even if we ignore the high variability of wind output, average wind output is low when customer demand is high
- We need storage to re-time the wind power
- We also need demand response or demand control to re-time the demand

Source: California ISO

# Methods of Coping with Wind Uncertainty

- Short-Term
  - ◆ Better wind forecasting
  - ◆ Carry more operating and spinning reserve to handle up and down ramps of wind output
  - ◆ Rapid coordination with demand response and energy storage
- Long-Term
  - ◆ Build more energy storage, e.g., Compressed Air Energy Storage (CAES)
  - ◆ Controllable demand response
  - ◆ Holistic planning of transmission, generation and demand

Potential wind curtailment

# What Were Achieved?

- Demonstration of the COCF prototype in the CAISO control center (5/2006)
- Developed and tested PCF for short term and long term congestion forecasting
- Workshop to present Functional Specs of COCF and results of PCF (11/2007)
- Final reports
- IEEE Paper

# COCF Validation on May 31, 2006

- Data preparation – May 30, 2006 (2 pm to 5 pm)
  - ◆ CAISO: Jim McIntosh, Jamal Batakji, Tamara Elliott, Dave Hawkins
  - ◆ EPRI: Steve Lee, Peter Hirsch, Guorui Zhang
  - ◆ Day-ahead load and resource forecasts
  - ◆ Identified major line outage = Round Mountain – Table Mountain #2 (500KV) resulting in COI limit derated to 2750 MW from 4800 MW
  - ◆ Request study assumptions on Summer 2006 Assessment for 1 in 10 Forecast
  - ◆ Familiarize with major paths to be monitored and forecasted
- May 31, 2006
  - ◆ 8:00 am to 2 p.m., Put COCF to the test
  - ◆ 2:00 pm, 1 Hour Review and Demonstration (Jim Detmers, Jim McIntosh, Patrick Truong, Dave Hawkins)

**Conclusion: COCF was capable of prediction for both the short term and also for the 1 in 10 Forecast case**

# Congested Paths Forecasted by PCF

Western Interconnect Congestion Areas, DOE Tasks 1-3 and 4. On-line:

# Graphic Output – Short-Term

With Typical Variation of  
Wind Generation

Probability of Congestion

With Assumed Constant  
Must-run Generation

# Graphic Output – Long-Term

More and More Wind Power is installed and integrated into the California system

Probability of Congestion

# What this Means for California?

With these tools, we can answer these policy questions:

- How much of the uncertainty about congestion comes from customer demand?
- How much reduction in congestion would come from managing load growth and demand side options?
- How much of the uncertainty about congestion comes from generator siting uncertainty, construction delay or retirement?
- How much of the uncertainty comes from renewable resources, especially wind power?
- How much of the uncertainty comes from electric vehicles?

# Conclusions

- Importance of both projects
- Benefits to California – Prevent blackouts and power crisis
- Valuable for Integration Study of Wind Power and Electric Vehicles
- Valuable for Holistic Planning of Transmission, Resources and Demands
